Supporting Information

ABSTRACT: Black crystals of $\text{Np}(\text{PS}_4)$, $\text{Np}(\text{P}_2\text{S}_6)_2$, $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$, and $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$ have been synthesized by the reactions of Np, P_2S_5 , and S at 1173 and 973 K; Np, K_2S , P, and S at 773 K; and Np, Rb_2S_3 , P, and S at 823 K, respectively. The structures of these compounds have been characterized by single-crystal X-ray diffraction methods. $\text{Np}(\text{PS}_4)$ adopts a three-dimensional structure with Np atoms coordinated to eight S atoms from four bidentate PS_4^{3-} ligands in a distorted square antiprismatic arrangement. $\text{Np}(\text{PS}_4)$ is isostructural to $\text{Ln}(\text{PS}_4)$ ($\text{Ln} = \text{La-Nd, Sm, Gd-Er}$). The structure of $\text{Np}(\text{P}_2\text{S}_6)_2$ is constructed from three interpenetrating diamond-type frameworks with Np atoms coordinated to eight S atoms from four bidentate $\text{P}_2\text{S}_6^{2-}$ ligands in a distorted square antiprismatic geometry. The centrosymmetric $\text{P}_2\text{S}_6^{2-}$ anion comprises two PS_2 groups connected by two bridging S centers. $\text{Np}(\text{P}_2\text{S}_6)_2$ is isostructural to $\text{U}(\text{P}_2\text{S}_6)_2$. $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ ($\text{A} = \text{K, Rb}$) adopts a three-dimensional channel structure built from interlocking $[\text{Np}_7(\text{PS}_4)_{13}]^{11-}$ -screw helices with A cations residing in the channels. The structure of $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ includes four crystallographically independent Np atoms. Three are connected to eight S atoms in bicapped trigonal prisms. The other Np atom is connected to nine S atoms in a tricapped trigonal prism. $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ is isostructural to $\text{A}_{11}\text{U}_7(\text{PS}_4)_{13}$. From Np–S bond distances and charge-balance, we infer that Np is trivalent in $\text{Np}(\text{PS}_4)$ and tetravalent in $\text{Np}(\text{P}_2\text{S}_6)_2$ and $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$. Np exhibits a behavior intermediate between U and Pu in its thiophosphate chemistry.

INTRODUCTION

Actinide elements and their compounds exhibit diverse chemical and physical properties owing to their accessible and partly filled 5f orbitals.¹ The 5f electrons show varying degrees of localization that range from itinerant band-like for light actinides to completely localized for elements Am and heavier. U, Np, and Pu are usually intermediate between these extremes.^{2,3} For this reason, these lighter actinides are particularly interesting. U, Np, and Pu compounds display extremely rich chemistries with a number of stable oxidation states, even in the same compounds.^{4–10} For example, the oxidation states of Np ions range from +3 to +7 in the redox window accessible in aqueous solutions.^{11,12} In contrast, their chalcogenide chemistries have been much less explored, especially for Np and Pu.^{7,10,13–19} In the known chalcogenide compounds, U is predominantly +4 with a few examples of +3 and +5.¹³ Np exhibits stable +3 and +4 oxidation states in chalcogenides, within which some are isostructural to U analogues (e.g., AMNpS_3 ($\text{A} = \text{K, Rb, Cs; M} = \text{Cu, Ag}$)¹⁴) and the rest are isostructural to lanthanide analogues (e.g., NpCuSe_2 ¹⁵). Pu is predominantly +3 in chalcogenides with most compounds being isostructural to lanthanide analogues.^{10,19}

Lanthanide (Ln) and actinide (An) oxophosphates have been extensively studied owing to their technological importance.

These include the monazite class of minerals, $\text{M}(\text{PO}_4)$ ($\text{M} = \text{trivalent light lanthanides or actinides}$). Monazite is a promising host for the incorporation of actinide waste because of its potentially high actinide content, sintering capability, and stability under extreme conditions.^{20–26} Although the chemistry of the oxophosphates and chalcophosphates differ because of their different redox properties and the weaker covalency of P–O bonds compared to P–Q ($\text{Q} = \text{S, Se}$) bonds, they have some comparative structural chemistry because of their similar anion geometries. A large number of actinide chalcophosphates, mainly of Th and U, have been synthesized during the past decade with the aid of reactive chalcophosphate fluxes.^{27–37} Th and U chalcophosphates have shown an extremely rich structural chemistry resulting from a combination of various P_xQ_y anions and metals of high coordination numbers in diverse binding modes. Both Th and U exhibit a stable +4 oxidation state in structures that range from three-dimensional frameworks to isolated clusters. Four Pu chalcophosphates are known, namely $\text{K}_3\text{Pu}(\text{PS}_4)_2$ and $\text{APu}(\text{P}_2\text{S}_7)$ ($\text{A} = \text{K, Rb, Cs}$).¹⁹ $\text{K}_3\text{Pu}(\text{PS}_4)_2$ is isostructural to $\text{K}_3\text{Ln}(\text{PS}_4)_2$ ($\text{Ln} = \text{Ce, La}$).^{38,39} The structure of $\text{APu}(\text{P}_2\text{S}_7)$ is related

Published: September 01, 2011

to that of $\text{KSm}(\text{P}_2\text{S}_7)$.⁴⁰ Thus, Pu thiophosphate chemistry is more lanthanide-like than that of Th or U. Remarkably, the chalcophosphate chemistry of Np, which lies between U and Pu, is unknown. Its position within the light actinide series provides an opportunity to examine structural systematics as the 5f orbitals fill and become more localized. Herein we present the syntheses and characterization of the first examples of Np thiophosphates: $\text{Np}(\text{PS}_4)$, $\text{Np}(\text{P}_2\text{S}_6)_2$, and $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ ($\text{A} = \text{K}, \text{Rb}$).

EXPERIMENTAL SECTION

Syntheses. K (Cerac, 98%), Rb (Strem, 99%), P_2S_5 (Aldrich, 99%), P (Aldrich, 99%), and S (Mallinckrodt, 99.6%) were used as received. Brittle ^{237}Np chunks were crushed and used as provided (ORNL). K_2S and Rb_2S_3 were prepared by stoichiometric reactions of the elements in liquid NH_3 .⁴¹

Caution! ^{237}Np is a α - and γ -emitting radioisotope and as such is considered a health risk. Its use requires appropriate infrastructure and personnel trained in the handling of radioactive materials. The procedures we use for the syntheses of Np compounds have been described.¹⁴

For all the reactions, the reactants were loaded into fused-silica ampules in an Ar-filled glovebox and then flame-sealed under vacuum. The reaction mixtures were placed in a computer-controlled furnace and heated according to a specific temperature profile. The reaction products were washed with DMF and dried with acetone. Single crystals found in these reactions were used in the determination of their crystal structures.

Np(PS₄). This compound was prepared through the reaction of Np (0.020 g, 0.084 mmol), P_2S_5 (0.019 g, 0.086 mmol), and S (0.003 g, 0.094 mmol). The reaction mixture was heated to 1173 K in 32 h, held at 1173 for 4 days, cooled to 773 K in 4.5 days, held at 773 for 2 days, and then cooled to 298 K in 6 h. The reaction products included large clusters of black irregular-shaped crystals of $\text{Np}(\text{PS}_4)$ and Np_3S_5^7 covered by a yellow powder. Only diffraction peaks from $\text{Np}(\text{PS}_4)$ and Np_3S_5 were found in the powder X-ray diffraction pattern of the product mixture. From the peak heights and areas, the yields of $\text{Np}(\text{PS}_4)$ and Np_3S_5 were roughly estimated to be 60% and 40%, respectively, based on Np.

Np(P₂S₆)₂. The same reaction mixture used for $\text{Np}(\text{PS}_4)$ was heated to 973 K in 20 h, held at 973 for 7.5 days, cooled to 673 K in 3.5 days, held at 673 for 10 h, and then cooled to 298 K in 5 h. The reaction products included large clusters of black irregular-shaped crystals of $\text{Np}(\text{P}_2\text{S}_6)_2$, $\text{Np}(\text{PS}_4)$, and Np_3S_5^7 covered by a yellow powder. Only diffraction peaks from $\text{Np}(\text{P}_2\text{S}_6)_2$, $\text{Np}(\text{PS}_4)$, and Np_3S_5 were found in the powder X-ray diffraction pattern of the reaction mixture. From the peak heights and area, the yields of $\text{Np}(\text{P}_2\text{S}_6)_2$, $\text{Np}(\text{PS}_4)$, and Np_3S_5 were roughly estimated to be 30%, 50%, and 20%, respectively, based on Np.

K₁₁Np₇(PS₄)₁₃. Black parallelepipeds of $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$ were obtained through the solid-state reaction of K_2S (0.014 g, 0.127 mmol), Np (0.019 g, 0.080 mmol), P (0.008 g, 0.258 mmol), and S (0.040 g, 1.25 mmol). The reactants were heated to 773 K in 16 h, held at 773 for 7 days, cooled to 373 K in 6 days, and then cooled to 298 K in 5 h. The products included many crystals of $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$ and unidentified black and yellow powders. The yield of $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$ was about 30% based on Np.

Rb₁₁Np₇(PS₄)₁₃. Black parallelepipeds of $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$ were obtained through the solid-state reaction of Rb_2S_3 (0.034 g, 0.127 mmol), Np (0.020 g, 0.080 mmol), P (0.008 g, 0.258 mmol), and S (0.032 g, 0.998 mmol). The reaction mixture was heated to 823 K in 16 h, held at 823 for 6 days, cooled to 423 K in 6 days, and then cooled to 298 K in 5 h. The products included many black crystals of $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$ and unidentified black and yellow powders. The yield of $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$ was about 20% based on Np.

Structure Determinations. Single-crystal X-ray diffraction data for $\text{Np}(\text{PS}_4)$ at 296 K and $\text{Np}(\text{P}_2\text{S}_6)_2$ and $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ ($\text{A} = \text{K}, \text{Rb}$)

^a For all structures, tetragonal system, $\lambda = 0.71073 \text{\AA}$. ^b $R(F) = \sum |F_o| - |F_c| / \sum |F_o|$ for $F_o^2 > 2\sigma(F_o^2)$. ^c $R_w(F_o^2) = \{\sum [w(F_o^2 - F_c^2)^2] / \sum w F_o^4\}^{1/2}$ for all data. $w^{-1} = \sigma^2(F_o^2) + (qF_o^2)^2$ for $F_o^2 \geq 0$; $w^{-1} = \sigma^2(F_o^2)$ for $F_o^2 < 0$. $q = 0.0198$ for $\text{Np}(\text{PS}_4)$, 0.0123 for $\text{Np}(\text{P}_2\text{S}_6)_2$, 0.0120 for $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$, and 0.0278 for $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$.

at 100 K were collected with the use of graphite-monochromatized $\text{MoK}\alpha$ radiation ($\lambda = 0.71073 \text{\AA}$) on a Bruker APEX2 diffractometer.⁴² The crystal-to-detector distance was 5.106 cm. Data were collected by a scan of 0.3° in ω in groups of 606 frames at φ settings of $0^\circ, 90^\circ, 180^\circ$, and 270° . The exposure time was 10 s/frame for $\text{Np}(\text{PS}_4)$, 60 s/frame for $\text{Np}(\text{P}_2\text{S}_6)_2$, 20 s/frame for $\text{K}_{11}\text{Np}_7(\text{PS}_4)_{13}$, and 30 s/frame for $\text{Rb}_{11}\text{Np}_7(\text{PS}_4)_{13}$. The collection of intensity data as well as cell refinement and data reduction were carried out with the use of the program APEX2.⁴² Face-indexed absorption corrections for $\text{Np}(\text{PS}_4)$ and $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$, and incident beam and decay corrections were performed with the use of the program SADABS.⁴³ The structures were solved with the direct-methods program SHELXS and refined with the least-squares program SHELXL.⁴⁴

The refinements of the structures of $\text{Np}(\text{PS}_4)$ and $\text{Np}(\text{P}_2\text{S}_6)_2$ were straightforward. The refinement of the structure of $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ involved a model for the disorder of the A(7) cation. The program STRUCTURE TIDY⁴⁵ was used to standardize the positional parameters. Additional experimental details are given in Table 1 and in the Supporting Information.

Powder X-ray Diffraction. Powder X-ray diffraction patterns were collected with a Scintag X1 diffractometer with the use of $\text{Cu K}\alpha$ radiation ($\lambda = 1.5418 \text{\AA}$).

Bond Valence Sum Calculations. Bond valences, V ,⁴⁶ were calculated from the formula $V = \sum_j \exp[-(R_0 - R_j/B)]$, where the sum is over the j atoms in the first coordination sphere, R_j is the bond distance between the metal center and the j th atom, and R_0 and B are bond-valence parameters. The program Bond Valence Calculator, Version 2.0⁴⁷, was used with $B = 0.37$.

RESULTS

Syntheses. Owing to our limited quantity of Np metal and its radioactivity hazard, numerous uranium thiophosphate reactions were conducted before we explored the neptunium system. The compound $\text{U}(\text{P}_2\text{S}_6)$ [$\text{U}^{4+}(\text{S}_3\text{P}_2\text{S}_3)^{2-}$]²⁸ was prepared in almost 100% yield from a reaction of U, P_2S_6 , and S in a molar ratio of 1:1:1 at 1173 K.⁴⁸ A similar reaction of Np to synthesize $\text{Np}(\text{P}_2\text{S}_6)_2$ failed. Instead, both $\text{Np}(\text{PS}_4)$ and Np_3S_5^7 were obtained. Several attempts to prepare pure $\text{Np}(\text{PS}_4)$ failed. For example, a stoichiometric reaction of Np, P_2S_6 , and S at 1248 K resulted in a mixture of $\text{Np}(\text{PS}_4)$ and Np_3S_5^7 . Surprisingly, one of

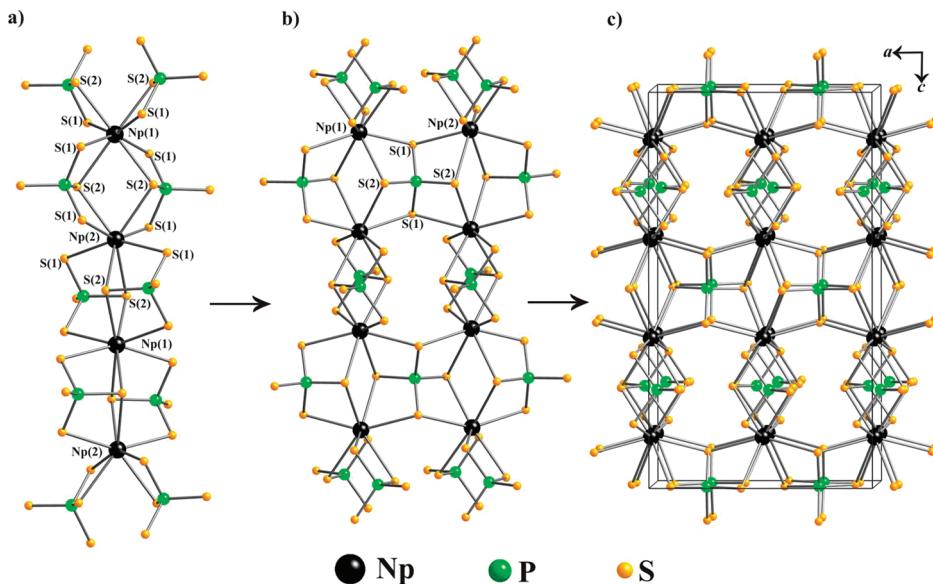

Figure 1. Crystal structure of Np(PS₄). (a) Single edge-sharing NpS₈ polyhedral chain along the [001] direction; (b) Two single NpS₈ polyhedral chains sharing corners with each other between Np(1)S₈ and Np(2)S₈ polyhedral on the ab plane; (c) NpS₈ polyhedral chain connecting to four neighboring chains to form the three-dimensional structure of Np(PS₄).

the failed reactions to prepare pure Np(PS₄) that involved an excess of thiophosphate flux at 973 K produced Np(P₂S₆)₂ (Np(S₂P⁵⁺S₂P⁵⁺S₂)₂). Several variations in stoichiometries and temperature regimes did not improve the yield of Np(P₂S₆)₂. Reactions somewhat similar to those used to prepare several alkali-metal U or Pu thiophosphates around 773 K did afford modest yields of A₁₁Np₇(PS₄)₁₃, whereas the U analogues, A₁₁U⁴⁺₇(PS₄)₁₃, were synthesized at 973 K.³⁶ Efforts made to prepare pure A₁₁Np₇(PS₄)₁₃ materials were not successful. Np(PS₄), Np(P₂S₆)₂, K₁₁Np₇(PS₄)₁₃, and Rb₁₁Np₇(PS₄)₁₃ were obtained in yields of about 60%, 30%, 30%, and 20%, respectively.

From the many Np reactions that were carried out it is clear that the solid-state syntheses of Np thiophosphates diverge from those of the U thiophosphates. This is not surprising because the redox chemistry of the metals and their melting points (U: 1405.3 K; Np: 910 K) differ. The lower melting point of Np metal compared to U allows a relatively lower reaction temperature to be used to achieve a reasonable diffusion rate of reactants.

Structure of Np(PS₄). Np(PS₄) crystallizes in the Pr(PS₄)⁴⁹ structure type in space group I4₁/acd of the tetragonal system. It is isostructural to Ln(PS₄) (Ln = La–Nd, Sm, Gd–Er).⁴⁹ The structure of Np(PS₄) includes two crystallographically unique Np positions (site symmetry of 222 for Np(1) and $\overline{4}$ for Np(2)) and one P position (site symmetry 2). Both Np centers are surrounded by eight S atoms from four bidentate tetrahedral PS₄³⁻ groups in a distorted square antiprismatic arrangement (Figure 1a), whereas each PS₄ tetrahedron shares an edge of S(1) and S(2) with two Np(1)S₈ and two Np(2)S₈ square antiprisms (Figure 1b). Each NpS₈ polyhedron shares an edge with two adjacent units in the fashion –Np(1)S₈–Np(2)S₈–Np(1)S₈–Np(2)S₈– to form one-dimensional chains along [001] (Figure 1a). Furthermore, each NpS₈ polyhedral chain connects to four neighboring chains by sharing corners between Np(1)S₈ and Np(2)S₈ polyhedra in the ab plane to form a three-dimensional framework with open channels in all three directions (Figures 1b and 1c).

The related U compound U_{0.75}(PS₄) is known.³³ It also possesses the Pr(PS₄)⁴⁹ structure type with the U(2) position

Table 2. Selected Interatomic Distances (Å) for Np(PS₄) and Np(P₂S₆)₂

	Np(PS ₄)	Np(P ₂ S ₆) ₂	
Np(1)–S(1) × 4	2.9309(5)	Np(1)–S(2) × 4	2.8579(8)
Np(1)–S(2) × 4	2.9702(5)	Np(1)–S(3) × 4	2.7997(9)
Np(2)–S(1) × 4	2.8839(5)	P(1)–S(1) ^a	2.107(1)
Np(2)–S(2) × 4	3.0419(5)	P(1)–S(1) ^a	2.115(1)
P(1)–S(1) × 2	2.0340(7)	P(1)–S(2)	1.990(1)
P(1)–S(2) × 2	2.0361(7)	P(1)–S(3)	1.996(1)
Np(1)…Np(2) × 2	4.8122(3)	Np(1)…Np(1) × 4	6.870(1)
Np(1)…Np(2) × 2	5.4262(3)	Np(1)…Np(1) × 4	9.766(1)

^a Bridging atom.

being half occupied. In this structure type, there are no S–S bonds. Consequently, the formal oxidation states of +3, +5, -2 may be assigned to Np, P, and S in Np(PS₄) and +4, +5, -2 to U, P, and S in U_{0.75}(PS₄).³³

Selected interatomic distances for Np(PS₄) are listed in Table 2. All the Np–S and P–S distances are very close to the corresponding ones in Nd(PS₄),⁴⁹ which is consistent with Np in the formal oxidation state +3. For example, the Np(1)–S distances are 2.9309(5) and 2.9702(5) Å vs Nd(1)–S distances of 2.934(2) and 2.971(2) Å; the Np(2)–S distances are 2.8839(5) and 3.0419(5) Å vs Nd(2)–S distances of 2.882(2) and 3.048(2) Å; and the P–S distances are 2.0340(7) and 2.0361(7) Å for Np vs 2.036(2) and 2.035(2) Å for Nd. Np–S distances are comparable to those found in Np₃S₅ for the eight-coordinate Np³⁺ cations, which are in the range of 2.8652(9)–3.024(1) Å.⁷ The Np(1)…Np(2) distances between two edge-sharing NpS₈ polyhedra are 4.8122(3) Å, and the distances between two corner-sharing NpS₈ polyhedra are 5.4262(3) Å.

In U_{0.75}(PS₄), U(1)–S distances are 2.863(2) and 2.895(2) Å, which are notably shorter than those of Np(1)–S.³³ If Np(1) and U(1) were in the same oxidation state, U(1)–S distances

would be expected to be about 0.02 Å longer than those of Np(1)–S because of the actinide contraction. In contrast, U(2)–S distances of 2.869(2) and 3.122(2) Å may be compared to Np(2)–S distances of 2.8839(5) and 3.0419(5) Å. This comparison is complicated because the U(2) position is only half occupied.

Structure of $\text{Np}(\text{P}_2\text{S}_6)_2$. $\text{Np}(\text{P}_2\text{S}_6)_2$ is isostructural to $\text{U}(\text{P}_2\text{S}_6)_2$ and crystallizes in the space group $I4_1/a$ of the tetragonal system.³² The structure of $\text{Np}(\text{P}_2\text{S}_6)_2$ contains one crystallographically unique Np position (site symmetry $\bar{4}$) and one P and three S crystallographically unique atoms in general positions. As shown in Figure 2, each Np atom is surrounded by eight S atoms from four bidentate $\text{P}_2\text{S}_6^{2-}$ groups in a distorted square antiprism. The P_2S_6 moiety comprises $\text{S}(2)\text{S}(3)\text{P}$ units bridged by S(1) atoms to give a centrosymmetric $\text{P}_2\text{S}_6^{2-}$ anion, which connects to two Np centers. Each resultant NpS_8 polyhedron connects to four other identical units to form adamantoid cages (Figure 3a). The structure of $\text{Np}(\text{P}_2\text{S}_6)_2$ consists of three interpenetrating adamantoid cage networks (Figure 3b). There are no S–S bonds in

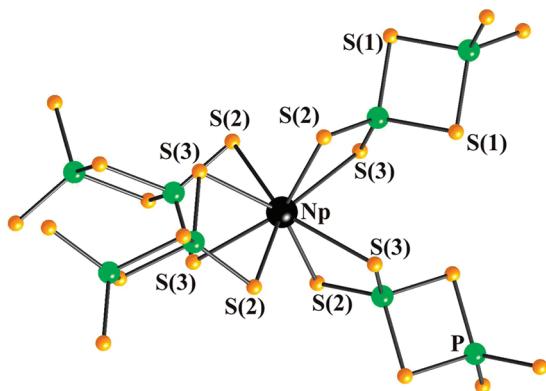

Figure 2. Coordination environment for the Np atom in $\text{Np}(\text{P}_2\text{S}_6)_2$.

the structure of $\text{Np}(\text{P}_2\text{S}_6)_2$; the formal oxidation states of Np, P, S may be assigned as +4, +5, –2, respectively.

Selected interatomic distances for $\text{Np}(\text{P}_2\text{S}_6)_2$ are presented in Table 2. Np–S distances are 2.8579(8) and 2.7997(9) Å, which are marginally shorter than the U–S distances of 2.879(1) and 2.812(1) Å in $\text{U}(\text{P}_2\text{S}_6)_2$, as expected.³² These Np–S distances may be compared with other Np–S distances reported for Np^{4+} systems. For example, from 2.681(2) to 2.754(1) Å for six-coordinate Np^{4+} cations in AMnPs_3 ($\text{A} = \text{K}, \text{Rb}, \text{Cs}; \text{M} = \text{Cu}, \text{Ag}$) compounds,¹⁴ from 2.6527(9) to 2.852(1) Å for the seven-coordinate Np^{4+} cations in Np_3S_5 ,⁷ and 2.889(2) and 2.9067(8) Å for nine-coordinate Np^{4+} cations in NpOS .⁵⁰ In $\text{Np}(\text{P}_2\text{S}_6)_2$, the P–S distances are 2.107(1) and 2.115(1) Å (bridging) and 1.990(1) and 1.996(1) Å (terminal), which are not statistically different from those of 2.107(2), 2.113(2), 1.989(2), and 1.997(2) Å in $\text{U}(\text{P}_2\text{S}_6)_2$.³² The $\text{Np}\cdots\text{Np}$ distance between two metal centers bridged by a $\text{P}_2\text{S}_6^{2-}$ group is 9.766(1) Å within an adamantoid cage and the closest metal distance between two neighboring cages is 6.870(1) Å.

Structure of $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ ($\text{A} = \text{K}, \text{Rb}$). $\text{A}_{11}\text{Np}_7(\text{PS}_4)_{13}$ is isostructural to $\text{A}_{11}\text{U}_7(\text{PS}_4)_{13}$.³⁶ The structure comprises seven crystallographically unique A, four Np, and seven P positions. Atoms Np(4), P(7), A(5), A(6), and A(7) have site symmetry 2, and the rest of the atoms are in general positions. Atoms Np(1), Np(3), and Np(4) are surrounded by eight S atoms from four bidentate tetrahedral PS_4^{3-} groups in bicapped trigonal prismatic arrangements, whereas each Np(2) atom is bound to nine S atoms from three bidentate and one tridentate tetrahedral PS_4^{3-} group in a tricapped trigonal prismatic geometry (Figure 4). Each $\text{P}(n)\text{S}_4$ ($n = 1, 2, 3, 4, 6, 7$) tetrahedron connects to two Np centers, whereas each $\text{P}(5)\text{S}_4$ unit connects to three Np atoms. Those NpS_x polyhedra connect to each other through bidentate PS_4^{3-} groups to form a $[\text{Np}_7(\text{PS}_4)_{13}]^{11-}$ helical chain that propagates along [001] (Figure 5). As shown in Figure 6, each $[\text{Np}_7(\text{PS}_4)_{13}]^{11-}$ chain further face and edge shares with

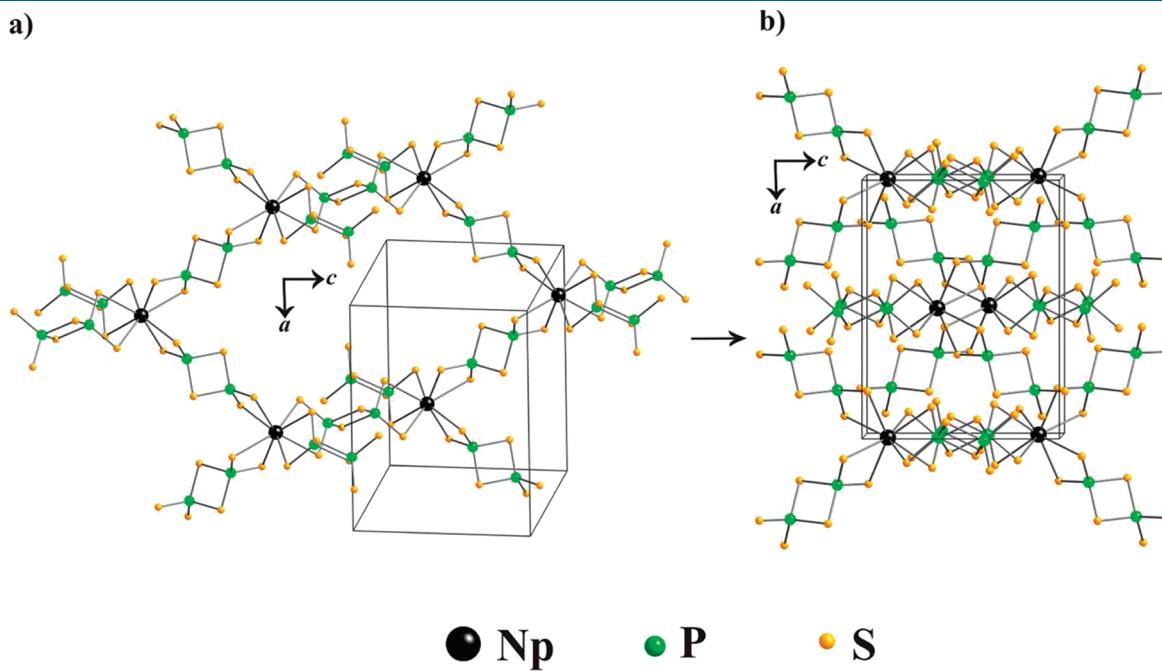

Figure 3. (a) Diamond-type framework in $\text{Np}(\text{P}_2\text{S}_6)_2$ constructed from adamantoid cages viewed down the [010] direction; (b) View of the three-dimensional structure of $\text{Np}(\text{P}_2\text{S}_6)_2$ down the [010] direction, which includes three interpenetrating diamond-type frameworks.

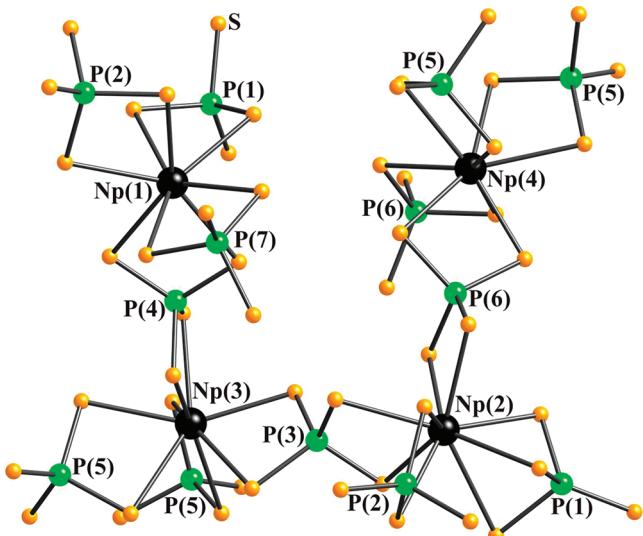

Figure 4. Coordination environments for four Np atoms and the connectivities between the neptunium sulfur polyhedra in $A_{11}Np_7(PS_4)_{13}$.

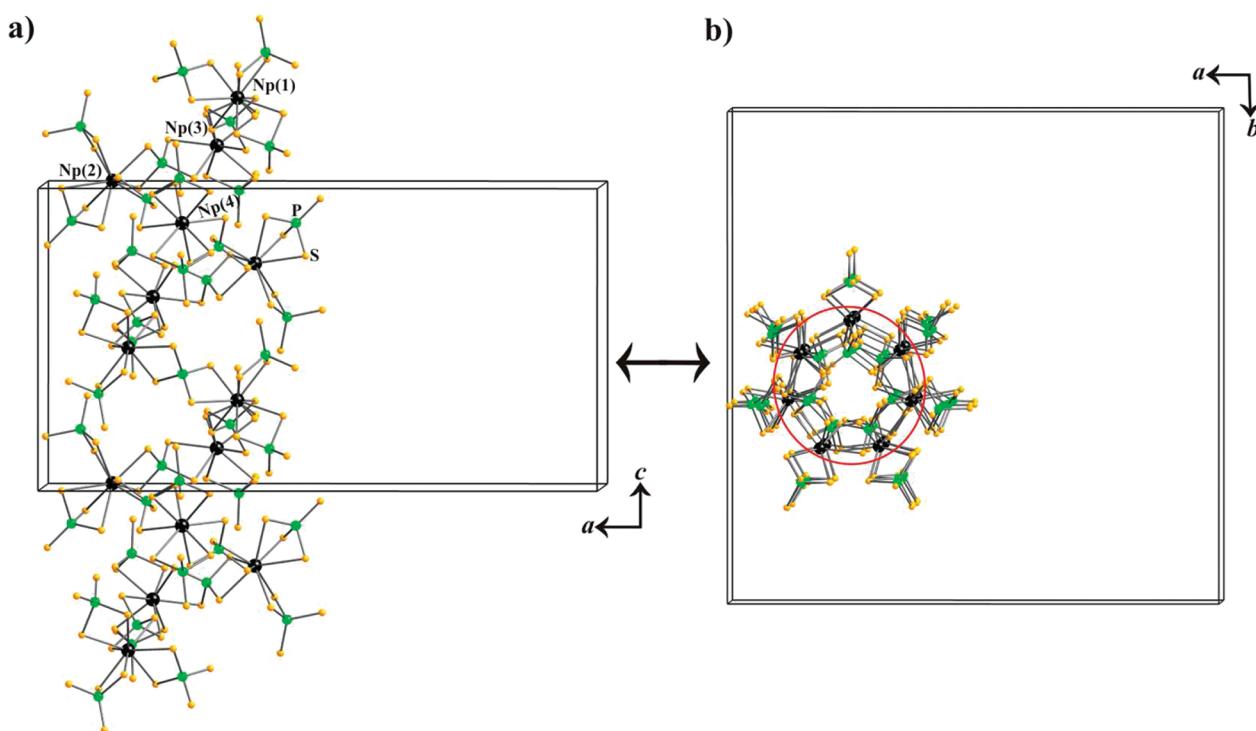

Figure 5. Single helical $[Np_7(PS_4)_{13}]^{11-}$ chain extending along the $[001]$ direction in $A_{11}Np_7(PS_4)_{13}$: (a) view down the b axis; (b) view down the c axis.

five neighboring chains on the ab plane to form a complex three-dimensional channel structure. The cavities created by $[Np_7(PS_4)_{13}]^{11-}$ chains are filled by the A atoms. There are no S–S bonds in the structure of $A_{11}Np_7(PS_4)_{13}$; charge balance is achieved with the formal oxidation states of A, Np, P, and S being assigned as +1, +4, +5, and -2, respectively.

Interatomic distances for $A_{11}Np_7(PS_4)_{13}$ may be found in the Supporting Information. Most of the Np–S and P–S distances for $K_{11}Np_7(PS_4)_{13}$ are within 0.01 Å of the corresponding ones in $Rb_{11}Np_7(PS_4)_{13}$. Only the distances for $K_{11}Np_7(PS_4)_{13}$ will

be discussed. Np–S distances range from 2.722(3) to 2.915(3) Å for eight-coordinate Np atoms and from 2.805(3) to 3.109(3) Å for the nine-coordinate Np(2) atom. These are generally slightly shorter than the U–S distances in $K_{11}U_7(PS_4)_{13}$ because of the actinide contraction. The U–S distances range from 2.722(4) to 2.942(4) Å for eight-coordinate U atoms and from 2.821(4) to 3.110(5) Å for the nine-coordinate U cation.³⁶ Np–S distances for the eight-coordinate Np atoms are in the same range as those found in $Np(P_2S_6)_2$, and the values for the nine-coordinate Np atom are comparable to those found in $NpOS$.⁵⁰ Most are longer

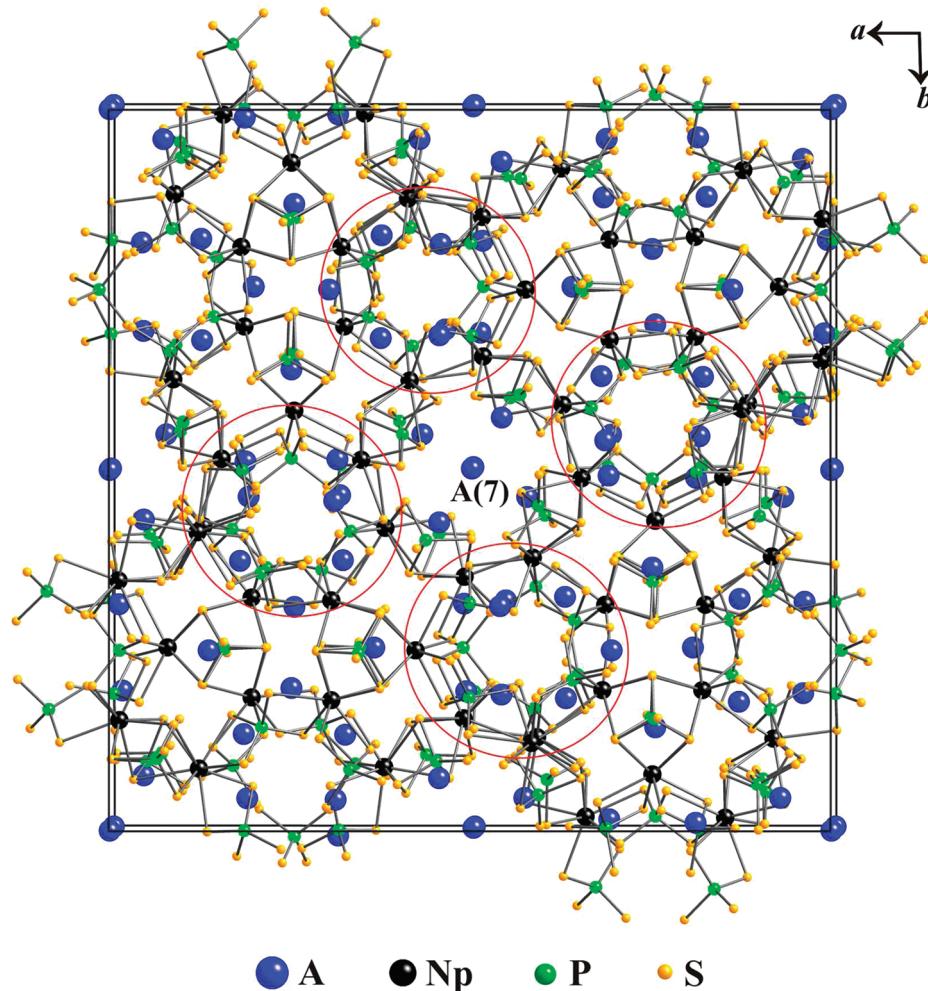

Figure 6. Each $[Np_7(PS_4)_{13}]^{11-}$ chain in $A_{11}Np_7(PS_4)_{13}$ shares faces and edges with five identical neighbors to form a three-dimensional channel structure, within which A^+ cations reside. $[Np_7(PS_4)_{13}]^{11-}$ chains are circled in red.

than those for the six-coordinate Np atoms in $AMNpS_3$ ($A = K, Rb, Cs; M = Cu, Ag$)¹⁴ and the seven-coordinate Np atoms in Np_3S_5 .⁷ The P–S distances are in the range of 1.962(4) and 2.150(5) Å, close to those of 1.936(7) to 2.084(6) Å found in $K_{11}U_7(PS_4)_{13}$.³⁶ K–S and Rb–S distances are comparable to those found in $A_{11}U_7(PS_4)_{13}$.³⁶ The Np···Np distances between two neighboring metal centers bridged by a PS_4^{3-} anion within each helical chain are in the range of 6.906(1)–6.9778(8) Å. The Np(1)···Np(2) distances between two face-sharing neptunium sulfide polyhedra in neighboring helical chains are 4.1413(6) Å, and the distances between two edge-sharing Np₈ polyhedra are 4.4219(8) Å for Np(3)···Np(3) and 4.3293(7) Å for Np(3)···Np(4).

Bond-Valence Analysis. Such an empirical analysis, when based on a multitude of literature data, provides an indication of the formal oxidation states of metal atoms in a given compound. However, there are too few Np–S distances available from single-crystal studies to make such an analysis meaningful. Instead, on the assumption that Np had a formal oxidation state of +4 in $AMNpS_3$ ($A = K, Rb, Cs; M = Cu, Ag$)¹⁴ and +3/+4 in Np_3S_5 ,⁷ a value of the necessary bond-valence parameter R_0 of 2.56 was obtained from the Np–S distances in $AMNpS_3$ and Np_3S_5 .⁷ Similar calculations were performed for the present four compounds (Table 3) on the assumption that the formal oxidation

states were +3 in $Np(PS_4)$ and +4 in $Np(P_2S_6)_2$, $K_{11}Np_7(PS_4)_{13}$, and $Rb_{11}Np_7(PS_4)_{13}$. The average value of R_0 is 2.57 for all ten compounds. The resulting valencies (Table 3) are reasonable.

■ DISCUSSION

The first four Np thiophosphates presented in the current study illustrate the divergence of Np thiophosphate chemistry from those of other early actinides. From single-crystal structural data and charge-balance considerations, Np cations are trivalent in $Np(PS_4)$ and tetravalent in $Np(P_2S_6)_2$ and $A_{11}Np_7(PS_4)_{13}$. With both stable +3 and +4 oxidation states, the thiophosphate chemistry of Np sits on the border between that of tetravalent U and trivalent Pu. Similar behaviors have been observed in their solution chemistry, which can be understood from a comparison of their relative An^{4+} standard reduction potentials (E°) in aqueous solutions under acidic conditions, −0.553(4) V for U, +0.22(1) V for Np, and +1.407(4) V for Pu.⁵¹ Whereas these potentials are not expected to be reproduced in the solid-state sulfides discussed here, their trend often predicts redox stability in an isostructural series in which the lattice potentials and Fermi levels remain relatively constant.^{52,53} From these potentials, it follows that among the three An^{3+} cations U^{3+} is the most susceptible to oxidation whereas Pu^{3+} is the least. In addition, the

Table 3. Bond-Valence Parameter R_0 and Bond Valence Sums

compound	atom	coordination number	assumed	valence	calculated from $R_0 = 2.57$
			oxidation state ^a	R_0^b	
Np(PS ₄)	Np(1)	8	+3	2.59	2.86
	Np(2)	8	+3	2.59	2.83
Np(P ₂ S ₆) ₂	Np(1)	8	+4	2.57	3.99
K ₁₁ Np ₇	Np(1)	8	+4	2.55	4.24
(PS ₄) ₁₃	Np(2)	9	+4	2.57	3.97
	Np(3)	8	+4	2.56	4.15
	Np(4)	8	+4	2.56	4.12
Rb ₁₁ Np ₇	Np(1)	8	+4	2.55	4.22
(PS ₄) ₁₃	Np(2)	9	+4	2.58	3.88
	Np(3)	8	+4	2.55	4.19
	Np(4)	8	+4	2.56	4.11

^a From charge-balance considerations. ^b These values average to $R_0 = 2.57$. The average value of 2.57 resulted from incorporation of all derived R_0 values from AMNp₃ (A = K, Rb, Cs; M = Cu, Ag), ¹⁴Np₃S₅,⁷ and the values above. This average value was used in a bond valence analysis to afford the tabulated valences.

reaction conditions, including the heating temperature and the presence of anions and other cations, can also affect the oxidation state of the final product. Np³⁺(PS₄)³⁻ was synthesized at a temperature 200 K higher than that of Np⁴⁺(P₂S₆)²⁻, presumably beyond the temperature necessary to decompose P₂S₆²⁻ anions to PS₄³⁻ anions. It is not surprising that the PS₄³⁻ anions attract the trivalent Np cations, while two P₂S₆²⁻ anions favor one tetravalent cation to form stable compounds. For the reactions of A₁₁Np₇(PS₄)₁₃, electropositive A⁺ cations may help to stabilize the higher valence of Np, Np⁴⁺, owing to the inductive effect.⁵⁴ The structural chemistry of Np thiophosphates is expected to be a combination of those of U⁴⁺ or Th⁴⁺ and Ln³⁺, which is well exemplified here, with Np(PS₄) isostructural to lanthanide analogues and Np(P₂S₆)₂ and A₁₁Np₇(PS₄)₁₃ isostructural to uranium analogues. In addition, compared to lanthanides and other lighter actinides, it is more likely for Np compounds to adopt new structure types containing both trivalent and tetravalent metal sites, as demonstrated by the mixed-valence binary compound, (Np³⁺)₂Np⁴⁺S₅⁷ found under those reaction conditions.

As noted in the Introduction, monazite (M(PO₄) (M = trivalent light lanthanides or actinides) has been studied for use as a solid-state matrix in a spent nuclear fuel repository. It is interesting to compare the structure of M(PS₄) with that of monazite. Similar to M(PS₄), the monazite structure contains interconnecting arrangements of metal polyhedral chains; however, each chain shares metal polyhedral edges with six neighboring chains to form a three-dimensional network without open channels.²² The metal polyhedra in monazite are much more close packed than those in M(PS₄). For example, the calculated densities from the X-ray structural data for Gd(PO₄)²² and Gd(PS₄)⁴⁹ are 6.00 and 3.83 g/cm³, respectively. This large structural deviation of M(PS₄) from that of Ln(PO₄) arises, at least in part, because there is less steric repulsion between the metal and P atoms for thiophosphates than for oxophosphates. For example, the Dy \cdots P distance between edge-sharing DyS₈ and PS₄ polyhedra in Dy(PS₄)⁴⁹ is 3.591 Å, whereas the Dy \cdots P

distance between edge-sharing DyO₈ and PO₄ polyhedra in Dy(PO₄)²² is 3.019 Å. As a result, PS₄³⁻ anions most commonly ligate large metal cations in multidentate modes, as shown here and in other actinide thiophosphates.^{19,27,33,35-37} In contrast, PO₄³⁻ anions more commonly bind large metal cations in a monodentate mode, as found in low valent actinide phosphates.⁵⁵ In the structure of M(PS₄), each metal center connects to four bidentate tetrahedral PS₄³⁻ groups, whereas the metal cation in the monazite structure is coordinated by nine O atoms from seven PO₄³⁻ groups, two of which are bidentate and the other five are monodentate.²² Clearly each metal center in the monazite structure binds to more ligands, which gives rise to a more dense structure than that of M(PS₄). One of the merits monazite has as a potential waste form for actinides is that it can accommodate most of the actinides without affecting the phase homogeneity. Trivalent actinide (U, Pu, Am-Bk) cations can readily replace the lanthanide cation because they have the same charge and similar radii. However, for substitution of the lanthanide by tetravalent actinides (Th, U, Np, Pu), charge balance has to be achieved by substitution mechanisms that involve the use of divalent cations such as Ca²⁺ or the SiO₄⁴⁻ anion.^{25,26} The orthothiophosphate structure type, because it can accommodate Ln³⁺, Np³⁺, as well as U⁴⁺ cations, is potentially superior to monazite as a waste form in this regard. Future research directions include syntheses and structural characterization of Th, Pu, and mixed lanthanide actinide orthothiophosphates as well as measurements of their electronic and magnetic properties.

CONCLUSIONS

Np(PS₄) is found to be isostructural to lanthanide analogues, whereas Np(P₂S₆)₂ and A₁₁Np₇(PS₄)₁₃ are shown to be isostructural to uranium analogues. Not only the charge-balance considerations but also comparisons of metric data indicate that Np is trivalent in Np(PS₄) and tetravalent in Np(P₂S₆)₂ and A₁₁Np₇(PS₄)₁₃. Thus, Np exhibits a behavior intermediate between U and Pu in thiophosphate chemistry. In addition, the present results have led to an improved bond-valence parameter R_0 for Np and to a better understanding of the change in Np-Q bond distances with oxidation states.
