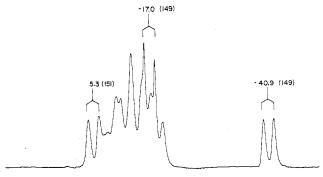

Figure 4. 70.6-MHz ¹¹B NMR spectrum of SeB₉H₉C·N(CH₃)₃ (solvent = CH_3CN).

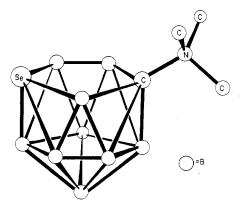

Figure 5. Proposed structure of SeB₉H₉C·N(CH₃)₃ (all hydrogen atoms have been omitted for clarity).

duction in coupling would lead to a doublet with narrower line width. In addition, all of the known nido 11-member heteroboranes²² exhibit a high-field doublet similar to the doublet observed at -40.9 ppm for SeB₉H₉C·N(CH₃)₃. This doublet can be attributed to the "apical" boron atom located at the bottom of the cage. On the basis of the NMR data, we propose the structure given in Figure 5 for SeB₉H₉C. $N(CH_3)_3$.

Linked and Mercury-Bridged nido-Carboranes. High-Yield Synthesis of μ,μ' -[(CH₃)₂C₂B₄H₅]₂Hg, Conversion to 5,5'-[(CH₃)₂C₂B₄H₅]₂, Cleavage, and Oxidative Addition of Benzene. Synthesis of μ,μ' -(B₅H₈)₂Hg

NARAYAN S. HOSMANE and RUSSELL N. GRIMES*

Received March 20, 1979

The *nido*-carborane anion $[2,3-(CH_3)_2C_2B_4H_5]^-$ reacts readily with anhydrous $HgCl_2$ in THF at room temperature, producing the bis(carboranyl)mercury(II) complex $\mu,\mu'-[(CH_3)_2C_2B_4H_5]_2Hg$ in which the metal is bound to two carborane ligands via B-Hg-B three-center, two-electron bridge bonds. On heating at 180 °C in benzene, this compound quantitatively expels free mercury and forms the B-B-linked nido-carborane 5,5'-[(CH₃)₂C₂B₄H₅]₂ as a single pure isomer. Air oxidation of the linked carborane in benzene solution results in cleavage of the carborane-carborane B-B bond and oxidative addition of benzene to give 4-C₆H₅-2,3-(CH₃)₂C₂B₄H₅, an apparently air-stable derivative of nido-2,3-C₂B₄H₈. Similar treatment of the linked carborane in C₆D₆ gives the corresponding hexadeuterated carborane product. The reaction of B₅H₈ ion with $HgCl_2$ in THF produces μ,μ' - $(B_5H_8)_2Hg$, a stable solid in which mercury is evidently bridge bonded to two pentaborane ligands.

Introduction

The small nido-carborane 2,3-C₂B₄H₈ and its substituted derivatives are exceedingly versatile ligands which readily form η^1 , η^2 , and η^5 complexes with metal and metalloid groups. Insertion of units such as $(CO)_3$ Fe or $(\eta^5-C_5H_5)Co^{2+}$ into the open face of the pyramidal species $R_2C_2B_4H_6$ (R = H, CH₃) or their anions $(R_2C_2B_4H_5^-)$ yields ${\it closo}$ -metallocarboranes in which the metal is η^5 bonded to the carborane and completes a seven-vertex MC₂B₄ polyhedral cage system. A rather extensive chemistry has been developed in this area1 including the oxidative fusion of face-bonded C₂B₄ ligands coordinated to the same metal ion to give tetracarbon C₄B₈ cages. In

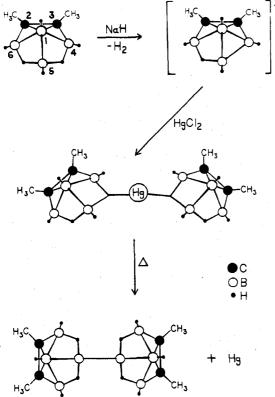

Figure 1. Scheme for the formation of $\mu,\mu'-[(CH_3)_2C_2B_4H_5]_2Hg$ (I) and its thermal conversion to 5,5'-[(CH₃)₂C₂B₄H₅]₂ (II). Only the isomer of I having C_s symmetry is shown; the product is presumably a mixture of the C_s and C_2 isomers. In both isomers, free rotation of carboranyl groups on the B₂-Hg axes is assumed.

contrast, the attack of monocoordinate units such as $(\eta^5-C_5H_5)Fe(CO)_2^+$, $[(C_6H_5)_3P]_3Rh^+$, $[(C_6H_5)_3P]_4u^+$, and R_3M^{IV+} (R = H, CH₃; M^{IV} = Si, Ge, Sn, Pb) on the $R_2C_2B_4H_5^-$ ion generates *bridge*-substituted complexes in which the metal is η^2 linked to the edge of the carborane cage by a three-center B-M-B bond.² In some cases these bridged species undergo thermal rearrangement to terminally η^1 -substituted isomers.

If an R₂C₂B₄H₅⁻ substrate is allowed to interact with a dicoordinate metal or metalloid group, one expects to form bis(carborane) complexes in which the metal participates in B-M-B three-center bonds on two different cages. The only reported example is μ, μ' -SiH₂(C₂B₄H₇)₂, prepared in this laboratory several years ago.^{2d} We are currently interested in doubly bridged complexes, in part because of their potential utility as precursors to linked nido-carboranes. These, in turn, open new areas for exploration in metallocarborane synthesis and structure (for example, Sneddon et al.³ have recently obtained a mixture of [(CH₃)₂C₂B₄H₅]₂ isomers in the mercury-sensitized photolysis of 2,3-(CH₃)₂C₂B₄H₆, and from this mixture prepared a number of linked cobaltacarborane complexes). In addition, it is likely that doubly bridged metal complexes are related to intermediates in the metal-promoted oxidative fusion⁴ of R₂C₂B₄H₄² ligands which generates tetracarbon carboranes such as R₄C₄B₈H₈.

We report here a simple and direct route for conversion of the $(CH_3)_2C_2B_4H_5^-$ ion to neutral, boron-boron-bonded 5,5'- $(CH_3)_2C_2B_4H_5^-H_5B_4C_2(CH_3)_2$ via a stable, isolable mercury-linked bis(carboranyl) complex. In addition, some novel chemistry of the linked carborane is described, and the closely related synthesis of μ,μ' - $(B_5H_8)_2Hg$ is reported.

Results and Discussion

Synthesis of μ,μ' -[(CH₃]₂C₂B₄H₅]₂Hg. The sodium salt of the 2,3-(CH₃)₂C₂B₄H₅ ion (obtained from the neutral car-

borane by deprotonation with NaH in tetrahydrofuran $(THF)^5$) was found to react easily at room temperature (even at -30 °C) with anhydrous mercuric chloride, forming the μ,μ' -bis(carboranyl)mercury(II) complex, I, in 87% yield (Figure 1). The product I was obtained by sublimation in vacuo as a white crystalline solid, mp 78 °C, that survives brief exposure to air and can be handled on the laboratory bench over limited periods. The compound was structurally char-

32.1-MHz ¹¹B FT NMR spectra of μ,μ' -[(CH₃)₂C₂B₄H₅]₂Hg (I) in CDCl₃: A, undecoupled; B, proton decoupled at 99.998 404 Hz. Chemical shifts and coupling constants are reported in Table I.

acterized from its unit- and high-resolution mass spectra (Experimental Section), ¹¹B, ¹H, and ¹³C NMR spectra (Tables I and II), and infrared spectrum (Table III).

The mass spectrum displays an intense parent grouping (cutoff at m/e 410) and strong groups with local cutoffs at m/e 307, 204, and 104 which correspond to the fragments $[(CH_3)_2C_2B_4H_5]Hg^+$, Hg^+ , and $(CH_3)_2C_2B_4H_6^+$, respectively; in each case the pattern of intensities is consistent with the composition indicated, on the basis of natural isotope distributions of boron and mercury.

The 32.1-MHz ¹¹B NMR spectrum (Figure 2) exhibits a high-field symmetric doublet corresponding to the apex B-H and an unsymmetric doublet at lower field assigned to overlapping B(4)-H, B(5)-H, and B(6)-H resonances; the chemical shifts (Table I) correspond closely to those of $2,3-(CH_3)_2C_2B_4H_6$ (δ -3.7, -7.2, and -47.7). The proton NMR spectrum (Table II) reveals two nonequivalent methyl environments and confirms the presence of bridging hydrogens, as shown by a broad, weak peak in the B-H-B region.

The location of mercury in a bridging, rather than a terminal, position on the cage¹⁷ can be inferred from the absence of a separate ¹¹B-Hg singlet in the undecoupled ¹¹B spectrum; terminal substitution on boron would be expected to produce a collapse of the 11B-H doublet to a singlet and a shift with respect to the unsubstituted boron resonance. Further support for the bridged structure is found in the infrared spectrum (Table III) which contains a split B-H stretching band near 2500 cm⁻¹, a feature which is exhibited by all known heteroatom-bridged C₂B₄H₈ derivatives but which is absent in terminally substituted species.²

Two isomeric arrangements are possible in I, one having C_s symmetry and the other C_2 . The NMR spectra give no indication of the presence of more than one isomer (which is not surprising since one would expect any differences in chemical shifts to be minute), and it is not possible to distinguish between the C_s and C_2 structures from available data. Indeed, it is probable that both isomers form in the reaction, since with the presumed linear (sp) hybridization of mercury the stereochemical preference for one arrangement over the other would be small. This problem is reminiscent of the question of structure in μ, μ' - $(C_2B_4H_7)_2SiH_2$ as discussed several years ago.2d In the silicon system, there was some indication, based on NMR resonances (H-Si), that the formation of the C_s isomer was favored (though both the C_s and the C_2 isomers form) in the reaction of C₂B₄H₇⁻ ion with SiH₂Cl₂. Evidently the tetrahedral hybridization on silicon and the presence of silyl hydrogens produce significant steric interaction between the carborane ligands and thereby lead to inequality in the

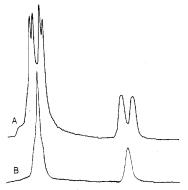

Figure 3. 32.1-MHz ¹¹B FT NMR spectra of 5.5'-[(CH₃)₂C₂B₄H₅]₂ (II) in C₆D₆: A, undecoupled; B, proton decoupled.

amounts of the two isomers formed. This is unlikely to be the

Compound I is the first confirmed example of a μ -mercury carboranyl complex, although we have reported the preparation of μ -(C₆H₅Hg)-C₂B₄H₇ as a partially characterized species which decomposed in air to release elemental mercury.2f Several mercury complexes of the $B_{10}H_{12}^{2-}$ ligand are known in which the metal is coordinated to one or two of the decaborane units; the mercury-borane linkages are probably η^4 , but bridged (η^2) structures have not been eliminated.⁷ A number of σ -mercury carboranyl complexes are known, all of them derived from the icosahedral 1,2-, 1,7-, or 1,12-C₂B₁₀H₁₂ carboranes.8 Most of these species involve Hg-C links, although a few examples of mercury substitution at boron in C₂B₁₀H₁₂ species have been reported.8b-d

Synthesis of $5.5'-[(CH_3)_2C_2B_4H_5]_2$. The mercury-bridged complex I at 180 °C in benzene expels mercury as the free metal and forms the bis(carborane) 5.5'-[(CH₃)₂C₂B₄H₅]₂ (II) in 91% yield (Figure 1). In addition to bulk experiments conducted on a 1-2-g scale, this conversion was monitored via proton NMR over an 18-h period and was observed to occur cleanly and quantitatively with no indications of the presence of intermediate species. Moreover, only one isomer (II) is formed insofar as can be detected.

The product II is a colorless liquid that can be distilled in vacuo at 70 °C. The ¹¹B, ¹H, and ¹³C NMR spectra indicate high (C_{2v}) symmetry with only one C-CH₃ environment and two boron signals in a 3:1 area ratio. The area-3 ¹¹B resonance (Figure 3) consists of a doublet of doublets arising from the equivalent B(4,6)-H groups in each cage, superimposed on the B(5)-B(5') singlet. The secondary splitting of the large doublet is due to coupling between the terminal protons on B(4,6) and B(4',6') and adjacent B-H-B bridging protons. The presence of the B(5)-B(5') singlet can be deduced from the slight asymmetry of the superimposed doublet and of the proton-decoupled (collapsed) peak in Figure 3B. Although equivalance of the four methyl groups could be produced by linkage either at B(5)-B(5') or at B(1)-B(1'), the latter possibility is eliminated by the fact that the apical boron resonance (which characteristically appears at high field in pyramidal boranes and carboranes⁹) is a doublet, showing that the apex borons retain their terminal hydrogens. In addition, of course, B(5)-B(5') linkage is much more easily reconciled with the synthesis from the bridged complex. The conversion of I to II with elimination of mercury is reminiscent of the formation of $(CH_3)_3Si-SiH_3$ from $(CH_3)_3Si-Hg-SiH_3$ at room temperature. ¹⁰

Compound II is the first pure isomer of a small linked nido-carborane to be isolated, although as mentioned above a mixture of [(CH₃)₂C₂B₄H₅]₂ isomers has been obtained by photolysis of (CH₃)₂C₂B₄H₆ in the presence of mercury. The only other example of a bis(nido-carborane) system to our knowledge is $(1,2-C_2B_9H_{11})_2$, which consists of linked ico-

sahedral-fragment moieties and was produced by oxidative

coupling of C₂B₉H₁₂⁻ anions with K₂CrO₄. ¹¹
Cleavage of 5,5'-[(CH₃)₂C₂B₄H₅]₂ and Oxidative Addition of Benzene. The linked carborane (II) is exceedingly air sensitive and in the absence of solvent reacts instantly with atmospheric oxygen at room temperature to produce a nonvolatile white solid that is insoluble in organic solvents. However, exposure to air of a solution of II in benzene gave remarkably different results, rapidly generating the 4-phenyl derivative of the monomeric carborane in nearly quantitative

yield (Figure 4).

The oxygenated product may be water, although this was not established.

Structural characterization of III, a colorless oil, was straightforward (Tables I-III); phenyl substitution obviously occurs at B(4), since the ¹¹B NMR (Figure 5) and proton NMR indicate low symmetry. When this reaction was conducted in benzene- d_6 , the mass spectrum of the product indicated a hexadeuterated species corresponding to C₆-D₅(CH₃)₂C₂B₄H₄D, indicating that all six hydrogens of benzene are retained in the product. Thus we formulate the

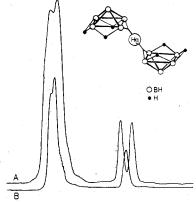

Figure 6. Proposed structure and ¹¹B FT NMR spectra of μ,μ' -(B₅H₈)₂Hg: A, undecoupled; B, proton decoupled.

reaction as an oxidative addition of benzene to (CH₃)₂C₂- $B_4H_5-H_5B_4C_2(CH_3)_2$ with concomitant cleavage of the central B-B link. As shown, one hydrogen from benzene is proposed to enter a bridging position, replacing a bridge hydrogen which moves to a terminal location on B(5). The phenyldimethylcarborane, III, appears to be reasonably air stable and does not decompose noticeably on handling in air over periods of a few hours. This property, combined with its low volatility and ready availability via the sequence described here, makes III a good candidate for extensive bench chemistry, including the synthesis of metallocarborane derivatives.

As a control experiment, a solution of II in cyclohexane was exposed to the atmosphere and was found to undergo only slow decomposition to insoluble white solids; in contrast to the oxidation in benzene, no substituted carboranes were detected.

Synthesis of μ,μ' -(B₅H₈)₂Hg (IV). The ease with which the bis(carboranyl)mercury complex I forms from (CH₃)₂C₂B₄H₅ and HgCl₂ led us to examine the analogous reaction of the B₅H₈ ion. The -30 °C addition of HgCl₂ to a THF solution of NaB₅H₈ gave white, crystalline, sublimable μ,μ' -(B₅H₈)₂Hg in nearly quantitative yield. The mass spectrum exhibits strong groupings with local cutoffs at m/e 330 (parent peak), 267, and 204, corresponding to $(B_5H_8)_2Hg^+$, $(B_5H_8)Hg^+$, and Hg^+ , respectively. The ¹¹B NMR spectrum (Figure 6) contains an apex B-H doublet which collapses to a singlet on proton decoupling, indicating that mercury attachment to the boron cage occurs at a basal and not an apical position; moreover, the presence of only one apex B-H resonance implies a symmetrical structure in which both B₅H₈ ligands are bound to the metal in identical fashion. The only such arrangements are μ,μ' - and 2,2'-(B₅H₈)₂Hg, and from NMR data the μ,μ' structure can be assigned. The near-superposition of the ¹¹B resonances of the basal boron atoms is more consistent with bridge than with terminal substitution; 32-MHz ¹¹B spectra of 2-metalated B₅H₉ derivatives usually exhibit clear nonequivalence of the basal borons. 12 The 11B-decoupled 1H NMR spectrum has superimposed basal H_{terminal} peaks, but the base:apex:bridge area ratio of 4:1:3 conforms with the bridged structure, as does the observation of strong 199Hg-1H_{terminal} coupling (Table II).

A number of bridged pentaborane complexes have been reported by Gaines and co-workers, 12a,c notably the μ -(R₃M)B₅H₈ series in which M is Si, Ge, Sn, or Pb and R is H or alkyl. The compound [(C₆H₅)₃P]₂CuB₅H₈, prepared by Brice and Shore, 13 has been shown to have a B-Cu-B bridge, as confirmed in an X-ray diffraction study.¹⁴ Several bis-(pentaboranyl) species of the type $(B_5H_8)_2MRR'$ $(M = Si, Ge; R = H, CH_3)$ are also known, 12c and these have been assigned μ ,2' or 2,2' structures. However, bis(pentaboranyl) complexes of the μ,μ' type have not, to our knowledge, been described prior to this work, nor have mercury-substituted pentaborane derivatives of any structural class been reported previously.

The possibility that IV may serve as an efficient precursor to a linked $(B_5H_8)_2$ species (whose three possible isomers have been obtained by other methods¹⁵) was not extensively studied, but pyrolysis of IV at 70 °C for 20 h gave B₅H₉, a small quantity of (B₅H₈)₂ (detected mass spectroscopically), elemental mercury, and nonvolatile solids.

The development of a simple high-yield route to linked nido-carboranes is of practical significance, since the linked compounds can serve as precursors to a variety of novel heterocarboranes, metallocarboranes, and tetracarbon carboranes. Indeed, this was the main rationale for initiation of this work. However, the unexpected observation of oxidative addition of benzene to the linked carborane opens up additional synthetic possibilities, particularly if such reactions prove to be general. We know of no precedent for oxidative addition of arenes to carboranes, and it is tempting to speculate that this process initially involves oxygen-promoted homolytic cleavage of the bis(carborane) to generate (CH₃)₂C₂B₄H₅. radicals which in turn combine with the solvent. Studies of the oxidation of $5.5'-[(CH_3)_2C_2B_4H_5]_2$ and similar linked carboranes in other solvents will be required to test this point.

Experimental Section

Materials. 2,3-Dimethyl-2,3-nido-dicarbahexaborane(8), 2,3-(CH₃)₂C₂B₄H₆, was prepared by reaction of 2-butyne with pentaborane(9) in the presence of triethylamine as described elsewhere. 16 All other reagents were commercially obtained and used as received.

Spectra. Boron-11 and proton pulse Fourier transform NMR spectra at 32.1 and 100 MHz, respectively, were recorded on a JEOL PS-100P spectrometer interfaced to a JEOL-Texas Instruments EC-100 computer system. Unit-resolution mass spectra were obtained on a Hitachi Perkin-Elmer RMU-6E mass spectrometer, while high-resolution mass measurements were conducted on an AEI MS-902 double-focusing instrument equipped with an SRI chemical ionization source. All high-resolution spectra were recorded under chemical ionizing conditions in methane or argon-water. Infrared spectra were obtained on a Beckman IR-8 instrument.

Preparation of $[2,3-(CH_3)_2C_2B_4H_5]_2Hg$ (I). $Na^+(CH_3)_2C_2B_4H_5^-$ (prepared by reaction of 5.94 mmol of 2,3-(CH₃)₂C₂B₄H₆ with excess sodium hydride in THF as described previously⁵) was dissolved in 30 mL of dry THF, and 3.00 mmol of anhydrous HgCl₂ was added on the vacuum line. After the mixture was stirred for 4 h at 25 °C, during which a white precipitate formed, 30 mL of hexane was added under a dry N₂ atomosphere. The solution was filtered through sintered glass, and the solvent was removed by vacuum distillation. The residue was heated at 70 °C in a sublimator under vacuum, and white crystalline I condensed on the cold finger which was maintained at -78 °C. The yield of I was 1.050 g (2.58 mmol, 87% based on starting carborane). Exact mass: calcd for $^{202}Hg^{12}C_8^{11}B_8^{1}H_{22}^{+}$, 408.2172; found, 408.2176. ^{13}C NMR (C_6D_6): sharp CH_3 peaks of equal area at δ 18.0 and 19.2 relative to Me₄Si.

Conversion of I to $[2,3-(CH_3)_2C_2B_4H_5]_2$ (II). A 1.31-g sample (3.21) mmol) of [(CH₃)₂C₂B₄H₅]₂Hg was placed under N₂ in a 30-mL Pyrex ampule fitted with a break-seal, 5 mL of dry benzene was added, the contents were frozen in liquid nitrogen, and the ampule was sealed under vacuum. The mixture was heated at 180 °C for 18 h, during which the originally colorless solution acquired a pale brown color and mercury globules collected at the bottom. During this period a parallel experiment was conducted on a smaller sample in a sealed Pyrex 5-mm NMR tube which was heated at 180 °C for 18 h with periodic monitoring of the 100-MHz ¹H NMR spectrum; in this way it was ascertained that the reaction reached completion with complete disappearance of the original spectrum.

The ampule was opened under vacuum, the contents were filtered under vacuum into a 50-mL flask, and the mercury which remained on the filter was washed with hexane, dried, and weighed; the yield was 0.66 g (3.26 mmol), corresponding to slightly greater than theoretical yield. The filtrate was stripped of solvent, and the liquid residue was distilled at 70 °C under vacuum into a trap cooled to 0 °C to give 0.60 g (2.91 mmol, 91% yield) of the colorless liquid

 $5.5'-[2.3-(CH_3)_2C_2B_4H_5]_2$ (II). Exact mass: calcd for ${}^{12}C_8{}^{11}B_8{}^1H_{22}^+$, 206.2466; found, 206.2477. ¹³C NMR (C₆D₆): sharp CH₃ peak at δ 21.0 relative to Me₄Si.

Oxidation of $[2,3-(CH_3)_2C_2B_4H_5]_2$ in Benzene. A 100-mg (0.48-mmol) sample of $5.5'-[(CH_3)_2C_2B_4H_5]_2$ (II) was dissolved in 5.0 mL of dry benzene, and this solution was shaken in air for 5 min, during which a small amount of white precipitate formed. The solution was filtered in air, and the solvent was removed by distillation under vacuum at 25 °C, which we continued for 2 h to remove the last traces of volatiles. The residue consisted of colorless, viscous 4-C₆H₅-2,3-(CH₃)₂C₂B₄H₅ (III) which was purified by distillation at 78 °C into a U-trap at 0 °C; yield 0.163 g (0.905 mmol, 94%). Exact mass: calcd for ${}^{12}C_{10}{}^{11}B_4{}^1H_{17}{}^+$ (protonated parent ion), 181.1703; found, 181.1712.

Synthesis of μ,μ' - $(B_5H_8)_2Hg$ (IV). A THF solution of Na⁺B₅H₈⁻ was prepared from 0.648 g (10.1 mmol) of B_5H_9 and 0.553 g (23.0 mmol) of NaH in 50 mL of THF and filtered in vacuo onto 1.32 g (4.84 mmol) of anhydrous HgCl₂ in a 250-mL round-bottom flask cooled to -78 °C. The solution was warmed to -30 °C and stirred for 2 h with little or no evolution of gas. After distillation of solvent out of the mixture at -30 °C over a 2-h period, a gray residue remained. To this residue was added 50 mL of dry hexane; the solution was filtered in vacuo, the solvent was returned to the flask containing the reaction residue, and the solution was filtered again. This process was repeated several times in order to extract most of the (B₅H₈)₂Hg, which is not highly soluble in hexane or other organic solvents. Evaporation of the solvent followed by sublimation of the product at 100 °C for 8 h gave 1.42 g (4.36 mmol, 90% yield) of pure white crystalline (B₅H₈)₂Hg, mp 161-162 °C (sealed capillary). The compound is moderately air stable, surviving exposure of several hours in the solid state without noticeable decomposition.

Pyrolysis of IV. A 0.656-g (2.0-mmol) sample of IV was placed in an evacuated Pyrex tube and heated for 20 h at 70 °C, after which the volatile products were fractionated through traps at -63 and -196 °C. The -196 °C fraction was nearly pure B₅H₉ (IR and mass spectra), 2.68 mmol. The -63 °C condensate was shown by mass spectroscopic analysis to consist of B₅H₉ and a small quantity of $(B_5H_8)_2$ (isomer not identified).

Complex Formation between the Aquopentacyanoferrate(II) Ion and Thiourea and Its N-Substituted Derivatives

DONAL H. MACARTNEY and ALEXANDER McAULEY*

Received March 28, 1979

The results of a kinetic investigation of the substitution reactions of pentacyanoaquoferrate(II) with thiourea and N-substituted thioureas are presented. The substitution rate constants, measured in the pH range 2.8-9.0, show a hydrogen ion dependence thoureas are presented. The substitution rate constants, measured in the pH range 2.8–9.0, show a hydrogen ion dependence $k_f = (k_{AH_2}[H^+]^2 + k_{AH_1}K_{AH_2}[H^+] + k_AK_{AH_1}K_{AH_2})/([H^+]^2 + K_{AH_2}[H^+] + K_{AH_1}K_{AH_2})$, which is consistent with the presence of three reacting species: HFe(CN)₅OH₂²⁻, Fe(CN)₅OH₂³⁻, and Fe(CN)₅OH⁴⁻. The acid dissociation constant for the aquo species has been determined $(K_{AH_1} = (1.37 \pm 0.20) \times 10^{-8} \text{ M})$. The aquo species is found to be more reactive toward thiourea $(k_{AH}(25 \, ^{\circ}\text{C}) = 202 \, \text{M}^{-1} \, \text{s}^{-1})$ than the hydroxy species $(k_A(25 \, ^{\circ}\text{C}) = 100 \, \text{M}^{-1} \, \text{s}^{-1})$ while the protonated aquo species $(k_{AH_2}(25 \, ^{\circ}\text{C}) = 2 \, \text{M}^{-1} \, \text{s}^{-1})$ is much less reactive. The dissociation rates of the Fe(CN)₅TU³⁻ (TU = thiourea) species are larger than those of complexes with N-donor ligands, indicating labile Fe-S bonds. An isokinetic plot of the activation parameters suggests different mechanisms operating in the formation (I_d mechanism) and dissociation (D mechanism) reactions of Fe(CN)₅TU³⁻ species.

Introduction

The reactions of pentacyanoferrate(II), Fe(CN)₅Lⁿ⁻, complexes are currently the subject of considerable interest, for several reasons. Mechanistic aspects¹⁻⁸ have been studied by using a variety of ligands and solvent systems since there is evidence for a dissociative, D, mechanism in the substitution of these complexes. In studies of complexes of this type where the volumes of activation have been measured, the data are consistent with this proposed mechanism. Also, these low-spin iron species represent models for active sites in biological systems, and reactions with imidazole have been investigated 10 in this regard. Another feature of these complexes is their use as the reducing center is the identification of precursor complexes in inner-sphere electron transfer. 11,12

To date, most of the studies have been undertaken for N-donor ligands, and relatively few data are available for sulfur-bonded complexes. In aqueous media, complexes are formed between Fe(CN)₅(OH₂)³⁻ and thiols or thioureas, the rates of formation being pH dependent. There is also a need for the study of the comparative reactivities of the pH-related forms of the pentacyanoferrate(II) ion. Davies⁸ has reported a value of $\sim 2 \times 10^{-7}$ M for the aquo-hydroxo equilibrium

$$Fe(CN)_5(OH_2)^{3-} \rightleftharpoons H^+ + Fe(CN)_5OH^{4-} K_{AH_1}$$
 (1)

Malin¹³ has shown that at low pH, protonation occurs (at cvanide)

$$H[Fe(CN)_5OH_2]^{2-} \rightleftharpoons H^+ + Fe(CN)_5OH_2^{3-} K_{AH},$$
 (2)

with a dissociation constant $K_{\rm AH_2}$ = (2.35 ± 0.6) × 10⁻³ M at 25 °C. The protonated species was found to be much less reactive than the aquo form.¹³ There are no rate constants available for the reaction of the hydroxo form. In this paper, we wish to report details of a kinetic study of the reaction with thiourea and several N-substituted thioureas. These ligands are particularly useful for identifying pH effects since there is no evidence for protonation¹⁴ over a wide (1-10) pH range, and the relative reactivities of the interrelated complex ions may be determined.

Experimental Section

Reagents. Sodium pentacyanoammineferrate(II) was prepared from sodium nitroprusside by the standard procedure. 15 The product was recrystallized from aqueous ammonia at 0 °C and washed with cold methanol. The dried yellow powder was stored under nitrogen in the dark at 5 °C. Thiourea (Fisher), allylthiourea (BDH), and N,N'dimethylthiourea (Ralph-Emanuel) were used after repeated recrystallization from water.

Kinetic Measurements. Studies were made by using a stopped-flow apparatus described previously. ¹⁶ The apparatus was thermostated to ± 0.05 °C. Formation reactions were monitored at 440 nm and dissociation reactions at 400 nm. The pentacyanoaquoferrate(II) ion was generated in solution by dissolving solid Na₃[Fe(CN)₅NH₃] in deoxygenated distilled water. Freshly prepared solutions of low concentration ($(2-4) \times 10^{-5}$ M) were used to prevent dimerization of the anion.^{17,18} In order to control the reaction pH, we used phosphate, phthalate, or borax buffers, since these were observed to have no effect on the reactant solutions and have in some instances been used in other studies.¹³ The ionic strength was maintained at 0.50 M by using sodium chloride.

All measurements were made under pseudo-first-order conditions with ligand in excess. Plots of $\ln (A_{\infty} - A_{i})$ against time derived from photographic traces of photomultiplier output were linear for at least

Spectra. The spectra of pentacyanoferrate(II) solutions (1.5×10^{-4}) M) were measured at various pH values by using a Varian Techtron 635 spectrophotometer over the range 350-500 nm. The sample cell holder was thermostated at the appropriate temperature (between 10 and 30 \pm 0.1 °C). Freshly prepared solutions of low complex concentration, adjusted to pH ~4, were deoxygenated and allowed to thermostat prior to each run. The hydrogen ion concentration was changed by addition of small volumes (0.01 mL) of 0.1 M NaOH, and after equilibration the shift in the spectrum was monitored. Measurements were made over the range pH 4-10, the pH values
